

SKELETONS: Museum of Osteology

Locomotion: Move like an Animal

Teacher Resource

Grade Levels: Pre-Kindergarten & Kindergarten

Kindergarten Oklahoma Academic Standards (OAS)

K-LS1-1 From Molecules to Organisms: Structure and Processes

K-LS1-1: Use observations to describe patterns of what plants and animals (including humans) need to survive.

K-ESS2-2 Earth's Systems

K-ESS2-2: Construct an argument supported by evidence for how plants and animals (including humans) can change the environment to meet their needs.

K-ESS3-1 Earth and Human Activity

K-ESS3-1: Use a model to represent the relationship between the needs of different plants or animals (including humans) and the places they live.

Program Overview:

Locomotion: Move like an Animal program will introduce students to various types of animal locomotion. The participants will observe the skeletal features that define a particular type of movement, and then mimic the movement of different types of animal locomotion.

Learning Objectives:

- Participants will successfully identify generalized skeletal features that define a particular locomotion.
- Participants will successfully work in a team environment and communicate their observations to their team.

Background:

Adaptation is a process of nature in which an animal becomes better suited to its habitat. Variations can be found throughout nature. In vertebrate species (animals with backbones), these adaptations often affect the skeletal system. One obvious example of skeletal adaptation can be found in locomotion.

Aerial Locomotion (“*Flight*”): is the act of flying. Skeletal adaptations aid in aerial locomotion by providing modified limb bones to form a wing as well as allow for muscle attachment. In bats, the only mammals capable of true flight, elongated arm and finger bones, combined with modified skin, form wings allowing them to fly.

Arboreal Locomotion (“*Tree Climbing*”): refers to species that live in and move through trees. These animals often possess physical adaptations that aid in this movement. These adaptations may include long limbs, prehensile tail, and claws. Animals that exhibit arboreal locomotion include squirrels, sloths, and monkeys.

Aquatic Locomotion (“*Swimming*”): as well as semi-aquatic locomotion, describes an animal’s movement in the water. Many species that live in the water possess aquatic locomotion to aid in their survival. Limbs

modified into flippers are one of the most common skeletal adaptations found in aquatic species. Some animals exhibiting aquatic locomotion include dolphins, sea turtles, and penguins.

Cursorial Locomotion (“Running”): is the type of locomotion most terrestrial animals use to move about. This form of locomotion primarily refers to running. Many species exhibiting this type of movement have developed skeletal adaptations such as longer limbs, the reduction of toes, modification of the feet and development of hooves. Some cursorial species are dogs, cats, horses, and gazelles.

Fossorial Locomotion (“Digging”): as well as semi-fossorial locomotion refers to the modified movement of animals that dig and live underground. These species often have modified limbs to aid in digging, as well as, compact bodies and rudimentary eyes. Some fossorial species include gophers, moles, and mole rats.

Saltatorial Locomotion (“Jumping”): animals that use hopping or jumping to move. Species utilizing this form of locomotion have evolved large, muscular hind limbs and often have reduced forelimbs. Some saltatorial species include rabbits, kangaroos, and gerbils.

Lateral Undulation (“Slithering”): the most common side-to-side motion of snakes. It is achieved by the snake contracting muscles on one side of its body and then the other, resulting in a serpentine motion. Snakes using this motion on land will usually push off of irregularities in the landscape using their belly scales. Other types of movement used by snakes are concertina, rectilinear, and sidewinding.

Vocabulary:

Adaptation: a process of nature in which an animal becomes better suited to its habitat

Carnivore: animals that primarily eat meat

Digging locomotion: movement of animals that dig and live underground

Flight locomotion: is the act of flying

Habitat: soil, water, climate, plants and animals of a particular ecosystem

Herbivore: animals that primarily eat plants

Jumping locomotion: movement of animals that hop or jump

Predator: animals that attack and eat other animals

Prey: animals that are attacked and eaten by other animals

Running locomotion: most land animals move about using this type of locomotion

Swimming locomotion: describes an animal’s movement in the water

Tree climbing locomotion: applies to animals that live in and move through trees

Slithering Locomotion: the side-to-side motion used by many snakes

While at SKELETONS:

- Have students visit the exhibits to identify the various types of locomotion that the creatures use to move about.
- Visit the Locomotion Exhibit and compare the skeletal structure of the Cheetah to other animals.
- Visit the Primate Exhibit to see how some primates utilize arboreal locomotion.
- Visit the Reptile Exhibit and discuss how the 20-foot Burmese Python is able to move from place to place without any limb bones.
- Have students look for the Lion chasing the Eland to see their predator-prey relationship in motion.
- Have students gently mimic the various types of locomotion in each exhibit.
